INTRODUCTION & CONTACT INFORMATION

OASIS-3 is the latest release in the *Open Access Series of Imaging Studies (OASIS)* that aimed at making neuroimaging datasets freely available to the scientific community. By compiling and freely distributing this multi-modal dataset, we hope to facilitate future discoveries in basic and clinical neuroscience. Previously released data for OASIS-Cross-sectional (Marcus et al, 2007) and OASIS-Longitudinal (Marcus et al, 2010) have been utilized for hypothesis driven data analyses, development of neuroanatomical atlases, and development of segmentation algorithms. OASIS-3 is a longitudinal neuroimaging, clinical, cognitive, and biomarker dataset for normal aging and Alzheimer's Disease.

The OASIS datasets hosted by central.xnat.org provide the community with open access to a significant database of neuroimaging and processed imaging data across a broad demographic, cognitive, and genetic spectrum an easily accessible platform for use in neuroimaging, clinical, and cognitive research on normal aging and cognitive decline. All data is available via www.oasis-brains.org.

OASIS-3 is a retrospective compilation of data for >1000 participants that were collected across several ongoing projects through the WUSTL Knight ADRC over the course of 30years. Participants include 609 cognitively normal adults and 489 individuals at various stages of cognitive decline ranging in age from 42-95yrs. All participants were assigned a new random identifier and all dates were removed and normalized to reflect days from entry into study. The dataset contains over 2000 MR sessions which include T1w, T2w, FLAIR, ASL, SWI, time of flight, resting-state BOLD, and DTI sequences. Many of the MR sessions are accompanied by volumetric segmentation files produced through Freesurfer processing. PET imaging from 3 different tracers, PIB, AV45, and FDG, totaling over 1500 raw imaging scans and the accompanying post-processed files from the Pet Unified Pipeline (PUP) are also available in OASIS-3.

ACCESS TO OASIS-3

Access to OASIS imaging, clinical, and biomarker data is available for access after completing the Data Use Agreement. Please log all data access requests using the online forms at www.oasis-brains.org.

- Data is available for access at https://central.xnat.org
- Further resources, including updated copies of this Data Dictionary, are available online at www.oasis-brains.org.
- Both OASIS: Cross-Sectional (OASIS-1) and OASIS: Longitudinal (OASIS-2) are available through the dataset tabs at www.oasis-brains.org.
- CONTACT INFORMATION: oasis-brains@nrg.wustl.edu

DATA USE AGREEMENT

The OASIS data are distributed to the greater scientific community under the following terms:

- 1. You will not attempt to establish the identity of to make contact with any of the included human participants.
- 2. You will acknowledge the use of OASIS data and data derived from OASIS data when publicly presenting any results or algorithms that benefitted from their use. Papers, book chapters, books, posters, oral

OASIS-3 Imaging Methods & Data Dictionary Version 1.8 Data Release: 1.2 Page | 4

presentations, and all other printed and digital presentations of results derived from OASIS data should contain the following:

- Acknowledgments: "Data were provided [in part] by OASIS [insert appropriate OASIS source info]"
 - OASIS: Cross-Sectional: Principal Investigators: D. Marcus, R, Buckner, J, Csernansky J. Morris; P50 AG05681, P01 AG03991, P01 AG026276, R01 AG021910, P20 MH071616, U24 RR021382
 - ii. OASIS: Longitudinal: Principal Investigators: D. Marcus, R, Buckner, J. Csernansky, J. Morris; P50 AG05681, P01 AG03991, P01 AG026276, R01 AG021910, P20 MH071616, U24 RR021382
 - iii. OASIS-3: Principal Investigators: T. Benzinger, D. Marcus, J. Morris; NIH P50AG00561, P30NS09857781, P01AG026276, P01AG003991, R01AG043434, UL1TR000448, R01EB009352. AV-45 doses were provided by Avid Radiopharmaceuticals, a wholly owned subsidiary of Eli Lilly.
- b. Citation: The specific publications that are appropriate to cite in any given study will depend on what OASIS data were used and for what purposes. An annotated and current list of OASIS publications is available at http://www.oasis-brains.org.
 - OASIS: Cross-Sectional: https://doi.org/10.1162/jocn.2007.19.9.1498 i.

OASIS PROJECTS AND CITATIONS

Each OASIS project should be used independently and not combined. Due to anonymization participants may be included in all three datasets under unique IDs.

- OASIS-1: Cross-Sectional T1w MR images across the lifespan (ages 18-96) with dementia status (doi: 10.1162/jocn.2007.19.9.1498)
- OASIS-2: Longitudinal T1w MR images in older adults (ages 60-96) with dementia status (doi: 10.1162/jocn.2009.21407)

OASIS-3 Imaging Methods & Data Dictionary Version 1.8 Data Release: 1.2 Page | 5 OASIS-3: Longitudinal MR and PET images (ages 42-95) with dementia status (doi.org: 10.1101/2019.12.13.19014902)

DATA RELEASES

RELEASE 1.0: MARCH 2018

- 1098 Subjects (age 42-95)
- Neuroimaging:
 - o 2118 MR Sessions
 - 1912 Freesurfer processed outputs
 - (TBD) PET Sessions
 - 1355 PET Unified Pipeline processed outputs
- Clinical and Cognitive Measures:
 - o 6217 Longitudinal Clinical follow-up assessments
 - 3342 Neuropsychological Assessments
 - o 4089 NACC UDS Assessments

RELEASE 1.2: APRIL 2018

o 1435 PET Sessions

CHANGE LOG RECORDS

SESSION MATCHUP

This script takes in two OASIS-3 .csv formatted spreadsheets and matches up the sessions based on your requested days from entry distance requirements. This script requires R at least version 3.3.0 and the R data.table library minimum version 1.12.8. See the R-project website for more details on the R language and visit the R data.table library website for more details on the data.table library.

OASIS-3 data has been anonymized and dates have been eliminated from the data set. OASIS-3 instead uses "days from entry" to note when scan sessions and questionnaire sessions happen

OASIS-3 Imaging Methods & Data Dictionary Version 1.8 Data Release: 1.2 Page | 7 relative to each other. The "days from entry" variable is seen in OASIS-3 IDs for MR sessions, PET sessions, Freesurfer assessors, PUP assessors, and questionnaire sessions (such as ADRC Clinical Data entries or UDS form entries). At the end of each ID is a string d0000 where 0000 is the days since the subject's entry date into the study. A days from entry value of 0 means that this is the subject's first visit.

OASIS FILE DESCRIPTION

BIDS FILE SPECIFICATION

All MR and PET imaging files are converted to nifti format utilizing the BIDS format (Gorgolewski et al., 2016). This allows for standardized naming and file formats. Raw MR files, in DICOM or IMA format were converted to Nifti format using dcm2nii (DICOM=dcm2niix v1.0.20171017 and IMA=dcm2nii mricronlx64-2013.06.12; Li et al., 2016). Raw PET imaging files were converted to Nifti format using dcm2nii (DICOM=dcm2niix v1.0.20171017 and ECAT7=dcm2niix v20170428). In addition to nifti files, a supplemental json file is included with additional acquisition header information, such as scanner model , TR, TE, flip angle, and PET info such as tracer, tracer dose, and injection timing , that is absent from nifti headers. Frame timing information for PET files can be found in the accompanying *.tsv file.

Documentation on BIDS can be found here (http://bids.neuroimaging.io/).

*Nifti conversion was completed after volumetric processing that has two big implications.

- First, any new processing of T1w.nii images through Freesurfer will result in different values as documented in FreeSurfer regarding file format changes.
- Second, the T1.mgz associated with the OASIS-3 Freesurfer processing is the result of dicom conversion to mgz and can be used in place of the T1w.nii file for comparative FreeSurfer processing.

MR IMAGING

MR SCANNERS

Data included in OASIS was collected on the following scanners. Scanner specific information is recorded in dataset_description.json for each MR scan session. For manuscripts, select only the scanner(s) from which your subset of data were derived.

Siemens BioGraph mMR PET-MR 3T scanner

- Siemens TIM Trio 3T MRI scanner (2 scanners)
- Siemens Sonata 1.5T scanner
- Siemens Vision 1.5T scanner

SCANNING METHODS

- Participants were placed in the scanner head to foot while lying in the supine position.
- Head immobilization was done by placing small foam cushions between the head and the head coil.
- In many participants, a Vitamin E capsule was used to mark the left temple.
- For all scans a 16-channel head coil was used.
- Participants receiving simultaneous PET acquisition, on the BioGraph mMR were injected with tracer prior to initiation of MRI scanning
- Note that not all subjects will have every type of image data.

DTI IMAGING

The OASIS-3 dataset includes 1205 DTI. All sequences include a *bvec and *bval file that includes information on the vectors and b-values as estimated through the dcm2niix conversion. These files are found in the BIDS folder associated with the DTI nifti. DTI sequences collected on Siemens scanners are known to have a variance of +/-10%. Below is the standard vector table for Siemens 25-direction DTI.

VECTOR TABLE FOR 25 DIRECTIONS

```

RESTING STATE SCANS

Resting state scans are labeled according to BIDS standard "task-rest". Slice timing is included in the JSON when available. Some original DICOM files did not have slice timing info. When slice timing information is unavailable use the ratio TR/#slices.

ASL PARAMETERS

The following parameters are important for processing ASL images but were not extracted into the JSON files as part of the BIDS conversion.

Scanner model	Software	TI1	TI2	Labeling	Slice	Background
	Version			Strategy	Readout	Suppression
51010	syngo_MR_B18P	700	1900	PASL	46.0ms	None
51010	syngo_MR_B20P	700	1900	PASL	46.0ms	None
35177	syngo_MR_B17P	700	1900	PASL	36.4ms	None
35248	syngo_MR_B17P	700	1800	PASL	36.4ms	None

POST-PROCESSED MRI: VOLUMETRIC SEGMENTATION

Single T1w MRI images were processed through Freesurfer to provide volumetric MRI data and segmentations maps. These maps can be used for a variety of purposes such as determining cortical volumes or regions of interest (ROIs) for PET imaging.

FREESURFER

OASIS-3 is a retrospective project that required anonymization of all files. In order to anonymize FreeSurfer output the following were removed: dates, timestamps, QC staff, raw file paths, original directory paths, ID change, and removal of all logs. OASIS-3 provides volumetric values representing Surface Measures from the aparc.stats Freesurfer output file and Subcortical Segmentation from the aseg.stats Freesurfer output file. These can be downloaded in csv format. All additional files, t1.mgz, brainmasks, segmentations, surface maps, and regional statistics.

*Conversion to BIDS format was completed following FreeSurfer processing. Segmantation of nifti files will produce different values than segmentation completed on dicom files and is documented by FreeSurfer. Direct comparison to OASIS-3 FreeSurfer files should be done using the T1.mgz file.

For a full description of Subcortical Segmentation and Surface Measures statistical variable see <u>list</u>.

PROCESSING BACKGROUND

FreeSurfer (http://surfer.nmr.mgh.harvard.edu/) analyses involved cortical reconstruction and volumetric segmentation of T1 weighted images. The technical details of these procedures are described in prior publications (Dale et al., 1999; Dale and Sereno, 1993; Fischl and Dale, 2000; Fischl et al., 2001; Fischl et al., 2002; Fischl et al., 2004a; Fischl et al., 1999a; Fischl et al., 1999b; Fischl et al., 2004b; Han et al., 2006; Jovicich et al., 2006; Segonne et al., 2004)). The processing pipeline included motion correction and segmentation of the subcortical white matter and deep gray matter volumetric structures on a T1 weighted image (Fischl et al., 2002), intensity normalization, registration to a spherical atlas which utilized individual cortical folding patterns to match cortical geometry across subjects (Fischl et al., 1999b), and parcellation of the cerebral cortex into units based on gyral and sulcal structure (Desikan et al., 2006).

All MRI sessions were processed through the FreeSurfer image analysis suite using Dell PowerEdge 1950 servers with Intel Xeon processors running CentOS 5.5 Linux.

- All 1.5T imaging data was reprocessed using FreeSurfer 5.0 or Freesurfer 5.1.
- All 3.0T MRI imaging data was reprocessed using FreeSurfer 5.3-HCP-patch.
- All data (1.5 and 3.0 T) have been corrected per the 2012 patch released by MGH.

QUALITY CONTROL MEASURES

All individuals were trained in the FreeSurfer quality control measures developed by the WU ADRC Imaging Core prior to interacting with the data. Such measures included processing pipeline workflows, visual inspection of the data for erroneous sessions, and the correct applications of edits to the volumes when errors persist. Additional information surrounding the FreeSurfer quality control process may be found through the FreeSurfer website, http://surfer.nmr.mgh.harvard.edu/fswiki/FsTutorial/TroubleshootingData.

OASIS-3 includes FreeSurfer output for sessions that were of quality "pass" or "pass with edits".

ANALYSIS CONSIDERATIONS

CORRECTING SUBCORTICAL AND CORTICAL VOLUMES FOR HEAD SIZE

It is suggested that all regions volumes should be corrected for head size (intracranial volume, ICV) in order to have correct comparisons. This does not apply to cortical thickness measures, as cortical thickness does not significantly vary with head size. The normalization process applies to each individual ROI and is sample specific. Please note if participants are removed from the data set the normalizations on the subcortical volumes will need to be re-run.

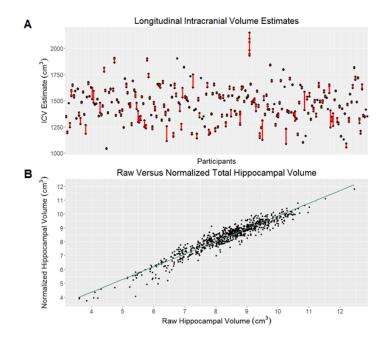

Note: Volume normalization must be repeated every time a subject is added or removed from the sample.

An analysis of the ICV estimate for each participant was performed on a longitudinal cohort (Figure 2). All participants had MRI scans using a 3T scanner and were processed with FreeSurfer 5.3. Within a participant, ICV can vary from baseline more than 5% with a mean subject standard deviation of 15.75 cm 3.

Relevant publication for the head-size correction:

Randy L. Buckner, Denise Head, Jamie Parker, Anthony F. Fotenos, Daniel Marcus, John C. Morris, and Abraham Z. Snyder A unified approach for morphometric and functional data analysis in young, old, and demented adults using automated atlas-based head size normalization: reliability and validation against manual measurement of total intracranial volume. Neuroimage, 2004.

Figure 2. (A) ICV estimate for each participant in a longitudinal study. Each black circle represents an MR session and the red line represents a longitudinal participant. (B) The relationship between the raw hippocampal volume and the hippocampal volume normalized by ICV.

INSTRUCTIONS FOR NORMALIZATION OF MRI FREESURFER-DERIVED CORTICAL VOLUMES

Normalization Calculation:

- 1. Compute mean ICV for sample
- 2. Compute regression with ICV as independent variable and ROI as dependent variable to obtain B (NOT Beta) weight
- Compute: Normalized = raw volume (B-weight * (ss ICV mean ICV))
 [Note: "ss" = single subject's]
- 4. This procedure is repeated for each subcortical & cortical ROI volume the investigator is interested in.
 - a. These volumes can be found in the "aseg.stats" file.
 - b. We do not normalize the cortical thickness measures.

Table 4. below shows a snapshot from the SPSS output for the linear regression. Use the B value highlighted in red for the correction factor. This will be repeated for each given ROI.

Coefficientsa

		Unstandardized Coefficients		Standardized Coefficients		
Model		В	Std. Error	Beta	t	Sig.
1	(Constant)	2718.207	343.943		7.903	.000
	ICV	-1.513E-5	.000	008	068	.946

a. Dependent Variable: transtemp

ADDITIONAL REGIONAL CALCULATIONS

Regional FreeSurfer outputs can be combined to generate multiple global brain measures that researchers may find useful (see https://surfer.nmr.mgh.harvard.edu/fswiki/MorphometryStats):

- Whole Brain Volume = Cortex + CorticalWhiteMatter + SubCortGray
- Cortex = IhCortex + rhCortex
- <u>CorticalWhiteMatter</u> = lhCorticalWhiteMatterVol + rhCorticalWhiteMatterVol
- <u>SubCortGray</u> = summation of thalamus, caudate, hippocampus, amygdala, accumbens, ventral DC, substanta nigra (if there). This is a simple voxel count of structures identified as subcortical GM.
- <u>Total Ventricular Volume</u> = left and right lateral inferior lateral ventricles + 3rd + 4th + 5th ventricles)

PET IMAGING

PET SCANNERS

Data included in OASIS was collected on the following scanners. Scanner specific information is recorded in dataset_description.json for each MR scan session. For manuscripts, select only the scanner(s) from which your subset of data were derived.

- Siemens Biograph mMR PET-MR 3T scanner (serial#: 51010)
- Siemens Biograph 40 PET/CT scanner (serial#:1003)
- Siemens ECAT HRplus 962 PET scanner

TRACERS

PIB

N-methyl-[11 C]2-($^{4'}$ -methylaminophenyl)-6-hydroxybenzothiazole ([11 C]PIB) is a radiolabeled compound that binds *in vivo* to brain amyloid deposits. Developed at the University of Pittsburgh, PIB has very high affinity for amyloid plaques. With administration of 6 - 20 mCi of [11 C]PIB, a 60 minute dynamic PET scan in 3D mode (septa retracted) will be initiated (24 x 5 sec frames; 9 x 20 sec frames; 10 x 1 min frames; 9 x 5 min frames).

AV45

Florbetapir binds to β -amyloid (A β) plaque utilizing the radioactive isotope 18F for use in PET scanning. Florbetapir F18 is used udner the research number 18F-AV-45 and therefore referred to as AV45. Participants received a single i.v. administration of 370 MBq (10 mCi) of florbetapir F 18 (over 10-60 sec). There are two acceptable procedures for obtaining the florbetapir F 18 PET scans:

- In the preferred approach, the participant will be positioned in the PET-MR scanner at the time of
 injection and a 70-minute dynamic scan (with simultaneous PET and full Standard MR acquisition) will be
 obtained starting at the time of injection. For florbetapir F 18 scans conducted on the PET/MR scanner, a
 short (approximately 15 minute) CT scan may be conducted on the PET/CT scanner.
- 2. For those participants who cannot tolerate the full exam, an alternative is to rest quietly in an uptake room for the first 40 minutes after injection. The participant will then be positioned in the PET-MR scanner to undergo a scan lasting 20 minutes, beginning 50 minutes after florbetapir F 18 injection and lasting for 20 minutes, using the Short MR Protocol. For florbetapir F 18 scans conducted on the PET/MR scanner, a short (approximately 15 minute) CT scan may be conducted on the PET/CT scanner.

FDG

Metabolic imaging with [18F]FDG-PET was performed with a 3D dynamic acquisition began 40 minutes after a bolus injection of approximately 5 mCi of FDG and lasted for 20 minutes.

POST-PROCESSED PET: PET UNIFIED PIPELINE (PUP)

PET imaging analyses are performed using the PET unified pipeline (PUP, https://github.com/ysu001/PUP) (Su 2013, Su 2015). PET images are smoothed to achieve a common spatial resolution of 8mm to minimize interscanner differences (Joshi et al., 2009). Inter-frame motion correction for the dynamic PET images is performed using standard image registration techniques (Hajnal et al., 1995; Eisenstein et al., 2012). PET-MR registration is performed using a vector-gradient algorithm (VGM; Rowland et al., 2005) in a symmetric fashion (i.e. average transformation for PET->MR and inverse of MR->PET was used as the final transformation matrix). By default, regional PET processing is performed based on FreeSurfer segmentation (using wmparc.mgz as the region definition), and each FreeSurfer region is analyzed. The PET processing pipeline generates both reports of regional measurements as well as an SUVR image in the individual FreeSurfer space.

PUP VARIABLE NOMENCLATURE

Our data naming convention provides a standard for listing the region and the processing method (Table 5a). Left and right brain structures use L and R. When left and right are averaged together the suffix includes the designation TOT. For a full list of variables see <u>PUP Variables</u>. Six prefixes are used:

Table 5a:

Data Type	Definition	Example Name
fBP_	FreeSurfer calculated Binding Potential	fBP_TOT_ACCUMBENS
fBP_rsf_	FreeSurfer calculated, partial volume corrected Binding Potential	fBP_rsf_TOT_ACCUMBENS
fSUVR_	FreeSurfer calculated SUVR	fSUVR_TOT_ACCUMBENS
fSUVR_rsf_	FreeSurfer calculated, partial volume corrected SUVR, the gold standard	fSUVR_rsf_TOT_ACCUMBENS

Table 5b:

Tracer	Definition	Example Name
PiB	[11C]-Pittsburg Compound B	PiB_fBP_TOT_ACCUMBENS
AV45	[18F]-Florbetapir	AV45_fSUVR_TOT_ACCUMBENS

The prefixes (tracer+processed_outcome) are applied to the SAS correlate suffix to create a descriptive SAS compliant name (Table 5b).

- PiB_fSUVR_rsf_TOT_CTX_PRECUNEUS is the [11C] PiB partial volume corrected SUVR of the gray matter in both the right and left FreeSurfer precuneus.
- PIB_fSUVR_rsf_TOT_WM_PRECUNEUS is the [18F] FDG partial volume corrected SUVR of the white matter calculated using the average activity in both the right and left FreeSurfer precuneus.
- PIB_fBP_TOT_CORTMEAN is the [18F] FDG average BP of the four MCBP cortical structures using FreeSurfer regions (TOTFS_PREFRN, TOTFS_TMP, TOTFS_GYREC, TOT_CTX_PRECUNEUS).

PARTIAL VOLUME CORRECTION

As PET images have low spatial resolution, measured signals are distorted by partial volume effects (PVE). The distortion caused by PVE is a function of the size and shape of the region of interest in addition to spatial resolution of the images. In longitudinal studies, the impact of PVE is further confounded by brain atrophy due to aging and pathological changes. To account for these distortions, correction technique is implemented in our processing pipeline using a regional spread function (RSF; Rousset 1998) based approach (Su 2015). We have demonstrated that the RSF technique was able to improve PET quantification and achieve better sensitivity to longitudinal changes in amyloid burden (Su 2015, 2016). Our standard PET processing includes results both with and without RSF partial volume correction. Also, SUVR images are only available without partial volume correction in current analysis.

AMYLOID PET IMAGING ANALYSIS

Currently, two amyloid imaging tracers are used in our studies, i.e. [11C]-Pittsburgh Compound B (PiB) and [18F]-Florbetapir (AV45). For both tracers, two modeling approaches are implemented: 1) binding potential (BPND) is calculated using Logan graphical analysis (Logan 1996; Mintun 2006; Su 2013, 2015, 2016), when full dynamic PET imaging data are available, i.e. PET acquisition was started in synchronization with tracer administration and PET images were reconstructed into multiple time frames; 2) regional target-to-reference intensity ratio, a.k.a, standard uptake ratio (SUVR), is estimated for all processable PET data. Under standard protocol, quantitative PET analysis (both BPND and SUVR) uses 30 to 60 minutes post-injection as the time window for PiB, and 50 to 70 minutes for AV45; and the cerebellum cortex is used as the default reference region. To assess global amyloid burden based on amyloid PET imaging data, the arithmetic mean of BPND or SUVRs from precuneus (PREC), prefrontal cortex (PREF), gyrus rectus (GR), and lateral temporal (TEMP) regions are defined as the mean cortical binding potential (MCBP) or mean cortical SUVR (MCSUVR). In FreeSurfer based processing, PREC is defined as the combined left and right hemisphere ctx-precuneus, PREF is defined as the left and right combined ctx-superiorfrontal and ctx-rostralmiddlefrontal regions, GR is defined as the left and right combined ctx-lateralorbitofrontal and ctx-medialorbitofrontal regions, and TEMP is defined as the left and right combined ctx-superialtemporal and ctx-medialorbitofrontal regions (Fig. 8; Su 2013).

CENTILOID CONVERSION FOR AMYLOID PET

Differences in the amyloid imaging tracer, the PET acquisition, and the analysis protocol across different studies introduce considerable variability within amyloid PET imaging data. This variability leads to difficulties in comparing and interpreting amyloid burden results reported from different groups (Klunk et al, 2015). To achieve comparable results, a standardized scale called Centiloid to convert mean cortical SUVR and BP into a Centiloid measure of *global amyloid disposition*. Regional values are unavailable for this dataset.

The procedure and requirements to define the Centiloid scale is documented in detail in the initial Centiloid paper (Klunk et al 2015). To summarize, the Centiloid scale is defined by two anchor points: the mean amyloid burden measurement of a young control group with no amyloid pathology in their brain, represented as 0 in the Centiloid scale, and the mean amyloid burden of an AD group, represented as 100 in the Centiloid scale (level 1 calibration). Subsequently, a Deming regression and a linear transformation are performed to calibrate the tracer and the local

processing methods to the Centiloid scale (i.e. level 2 calibration). Both PiB and AV45 have been calibrated to the Centiloid scale for both non-partial volume and partial volume correction (rsf) using standard PUP (Su, in prep).

Table 6. Examples of the conversion between non-partial volume corrected SUVR and BP to their respective Centiloid value.

Centiloid Value	PiB 30-60 min BP	PiB 30-60 min SUVR
-10	-0.0442	0.9776
0	0.0347	1.0671
25	0.2320	1.2907
50	0.4294	1.5143
75	0.6267	1.7379
100	0.8240	1.9615
110	0.9029	2.0510

CUTOFF VALUES FOR AMYLOID POSITIVITY

Traditionally, the cutoff for amyloid positivity has been established as MCBP>0.18 based on manually processed PiB data (Mintun 2006). We also established that the same cutoff could be used for FreeSurfer processing generated MCBP based on a study population of 77 participants (Su 2013). Based on this dataset, the cutoff for MCSUVRRSF was determined to be 1.42, the cutoff values for additional versions of global amyloid burden measurements that would generate best matched amyloid positivity classification as using manual MCBP=0.18 are also determined. For AV45, the equivalent cutoff to PiB MCSUVRRSF>1.42 was determined based on a sporadic AD cohort of 103 participants who had AV45-PiB crossover data based on the regression line between AV45 MCSUVRs and PiB MCSUVRRSF (Fig. 3) (Su 2018). The equivalent cutoffs in Centiloid units were also derived by applying the Centiloid conversion equations to the native measurement cutoffs.

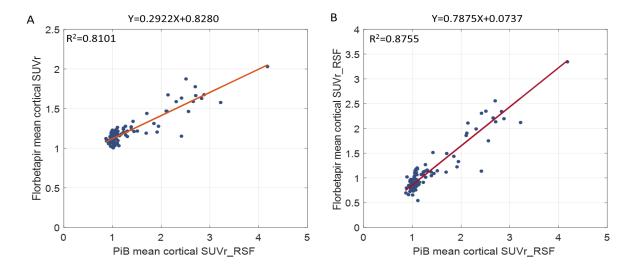

Figure 3. PiB-AV45 crossover dataset illustrating the relationship between AV45 based mean cortical SUVR and PiB based mean cortical SUVRs.

PUP VARIABLES

Below is a list of the Pet Unified Pipeline (PUP) variables as found in OASIS-3 and a suggested list of SAS compatible labels. The prefixes (tracer+processed_outcome) are applied to the SAS correlate suffix to create a descriptive SAS compliant name (ex: PiB_mSUVR_TOT_ACCUMBENS).
